

## A WEB- BASED HEALTHCARE MANAGEMENT SYSTEM

### HARDWARE AND SOFTWARE COMPONENTS REQUIRED.

Software development life cycle processes includes

1. Requirement analysis
2. Planning
3. Design
4. System Development
5. Testing
6. Deployment

#### **Requirement analysis**

The main concept for this type of system is a web-based health care management system. For effective COVID19 healthcare, a network system monitoring ones vital signs and evaluating ones health conditions is highly desirable. In our laboratory, we have developed a vital ensing system for home healthcare. The purpose of this study is to design and implement a prototype web-based healthcare management system (WBHMS) to make effective use of the data that are measured by the vital sensing system.

#### **Planning**

When it comes to designing a system, we ensure that we employ an independent web-based system for its easy use. Then we consider security and privacy because the personal data are handled through the Internet. Moreover, we consider that the users are supposed to be able to check not only the data from the vital sensing system but also the analyzed report as

feedback

**Hardware requirements** list is often accompanied by a hardware compatibility list (HCL), especially in case of operating systems. An HCL lists tested, compatibility and sometimes incompatible hardware devices for a particular operating system or application. The following sub-sections discuss the various aspects of hardware requirements. These include, Intel dual Core, i3 And above as the processor of the OS, Internet connection for the health center, clinical thermometer.

While the **Software Requirements** deal with defining software resource requirements and prerequisites that need to be installed on a computer to provide optimal functioning of an application.

### Design

A well designed algorithm for a web-based COVID19 Healthcare Management System

STEP1: Start

2: Body status to the virus=0

3: Add the COVID19 symptoms in the system

4: Put the software involved

5: Create a questionnaire

6: Collect qualitative data

7: Analyze Data

8: Body Status positive to the virus

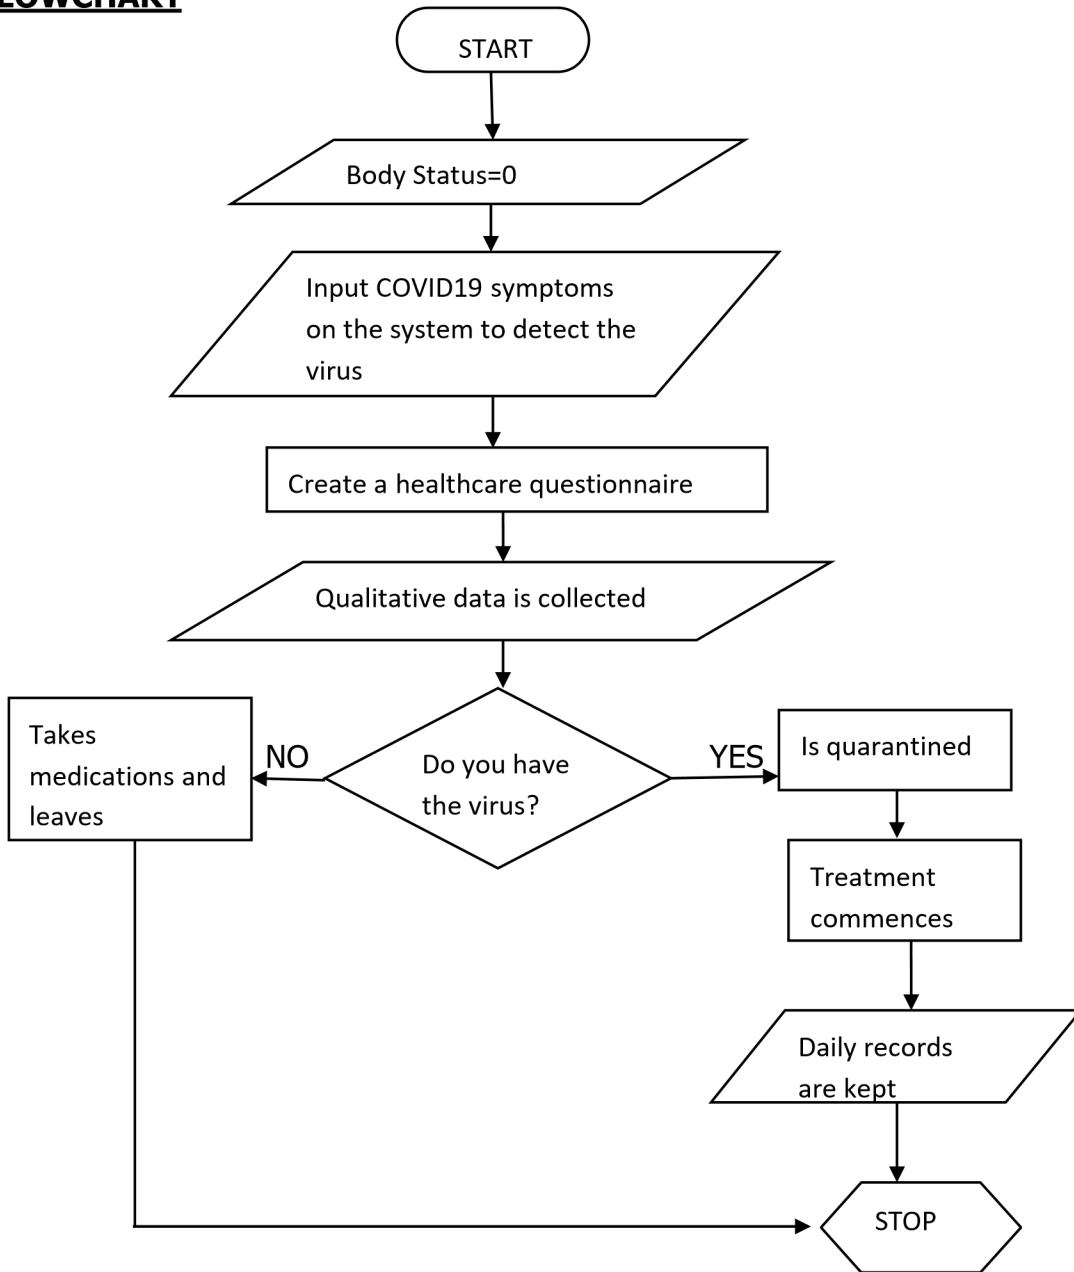

9: Else

10: Body Status negative to the virus

11: Display feedback

STEP12: Stop.

**FLOWCHART**

**System development**

The data viewer function provided graphs of physiological data, which are body temperature, blood pressure, pulse wave (PW), and electrocardiograph (ECG), measured by the vital sensing system.

### Testing

The COVID19 Healthcare web apps need to be fool-proof, which is why testing the apps and their functionalities become so important. Right from testing the security and compliances to the workability and the integration of the app, testing can also be done with different operating systems, internet connections and hardware.

### Deployment

This application is being released to detect, display the rate of virus, store, transmit and access data through the web together and its updated when necessary based on the health center feedback

### TOP- DOWN DESIGN APPROACH OF THE APPLICATION
