

UNOPENED QUEEN FREDRICK

CH₃ IO₂ (AASSICNORTU OR ETHER)

IUPAC Name - Methoxy methane

IUPAC Name - Ethoxyethane

IUPAC Name - 2-Methoxyidyl Propane

IUPAC Name - Methoxyethane

IUPAC Name - Ethoxypropane

2. i. Polarity: Since the electronegativity of oxygen is greater than that of carbon, ethers are polar in nature. Moreover, the two C-O bonds in ether are inclined to each other at an angle of 110°, so the dipoles do not cancel each other, resulting in a net dipole moment.

ii. Boiling point: The boiling point of ethers is lower than that of isomeric alcohols because ethers do not form H-bonds within themselves. Solubility: Lower ethers (up to three carbon atoms) are soluble in water because they form hydrogen bonds with water molecules. Others are:

- i. Preparation by Williamson Synthesis
In this method, an alkyl halide is reacted with sodium alkoxide which leads to the formation of ester. The reaction generally follows the S_N2 mechanism for polar alcohol formation.
- ii. Preparation by dehydrohalogenation of Alcohols
This method is a nucleophilic substitution reaction. The alcohol involved in reaction plays two roles: one alcohol involved plays two roles: one alcohol molecule acts as a nucleophile while the other acts as a nucleophile. It can follow an S_N1 or S_N2 mechanism before or simultaneously upon the attack of a second alcohol molecule.

iii. Density: Ethers are lighter than water.

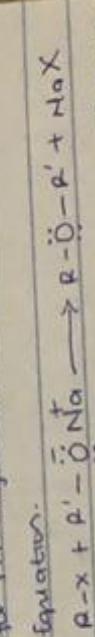

iv. Density: Ethers are lighter than water.

v. Solubility: Lower ethers (up to three carbon atoms) are soluble in water because they form hydrogen bonds with water molecules. Others are:

- i. It is used to make antifreeze, adhesives, detergents, polyester, etc.
- ii. It is used as a fungicide in certain agricultural products and as a sterilant for medical equipments and supplies.
- iii. It is produced on large volumes and used in the production of several industrial chemicals.

3. Preparation by Williamson Synthesis

In this method, an alkyl halide is reacted with sodium alkoxide which leads to the formation of ester. The reaction generally follows the S_N2 mechanism for polar alcohol.

ii. Preparation by dehydrohalogenation of Alcohols

This method is a nucleophilic substitution reaction. The alcohol involved in reaction plays two roles: one alcohol involved plays two roles: one alcohol molecule acts as a nucleophile while the other acts as a nucleophile. It can follow an S_N1 or S_N2 mechanism before or simultaneously upon the attack of a second alcohol molecule.

iii. Boiling point: The boiling point of ethers is lower than that of isomeric alcohols because ethers do not form H-bonds within themselves. Solubility: Lower ethers (up to three carbon atoms) are soluble in water because they form hydrogen bonds with water molecules. Others are:
