1a) Consider a negatively charged rubber rod brought near a neutral (uncharged) conducting sphere that is insulated so that there is no conducting path to the ground as shown below. The repulsive force between the electrons in the rod and those in the sphere causes a redistribution of charges on the sphere so that some of electrons move to the side of the sphere farthest away from the rod. The region of the sphere nearest the negatively charged rod has an excess of positive charge because of the migration of electrons away from the location. If a grounded conducting wire is connected to the sphere, some of the electrons leave the sphere and travel to the earth. If the wire to the ground is then removed, the conducting sphere is left with an excess of induced positive charge.

Finally, when the rubber rod is removed from the vicinity of the sphere the induced positive charge remains on the ungrounded sphere and become uniformly distributed over the surface of this sphere.

6) Solution

$$q_1 + q_2 = 5 \times 10^{-5} \text{ C}$$

$$q_1 = 5 \times 10^{-5} - q_2$$

$$F = \frac{k q_1 q_2}{r^2}, 100 = \frac{9 \times 10^9 q_1 q_2}{2^2}$$

$$4 = 9 \times 10^9 (5 \times 10^{-5} - q_2) q_2$$

$$4 = 4.5 \times 10^5 q_2 - 9 \times 10^9 q_2^2$$

$$-9 \times 10^9 q_2^2 + 4.5 \times 10^5 - 4 = 0$$

Using the quadratic formula; $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

$$q_2 = \frac{-4.5 \times 10^5 \pm \sqrt{(4.5 \times 10^5)^2 - 4(-9 \times 10^9)(-4)}}{2(-9 \times 10^9)}$$

$$q_2 = \frac{-4.5 \times 10^5 \pm \sqrt{5.8 \times 10^{10}}}{-18 \times 10^9}$$

$$q_2 = -4.5 \times 10^5 \pm 241867.7$$

$$-18 \times 10^9$$

$$q_2 = 1.156 \times 10^{-5} \text{ or } 3.84 \times 10^{-5} \text{ C}$$

$$q_1 = 1.156 \times 10^{-5} \text{ C}$$

$$q_2 = 3.84 \times 10^{-5} \text{ C}$$

$$E_2 = \frac{kQ_2}{r^2} = \frac{(9 \times 10^9) \times (12 \times 10^{-9})}{3^2} = 12 \text{ N/C}$$

36 The magnetic flux is defined as the strength of a magnetic field ^{represented} by lines of force. It is usually represented by the symbol Φ .

6 $m_e = 9.11 \times 10^{-31} \text{ kg}$, $r = 1.4 \times 10^{-7} \text{ m}$, $\theta = 90^\circ$ $\sin \theta = 1$

Magnetic field = $3.5 \times 10^{-1} \text{ Weber/meter square}$

$$\omega = \frac{qB}{m} = \frac{1.6 \times 10^{-19} (3.5 \times 10^{-1})}{9.11 \times 10^{-31}} = 6.15 \times 10^{10} \text{ rad/s}$$

An electron of mass 9.1×10^{-31} kg and charge 1.6×10^{-19} C in motion in a magnetic field of 5×10^{-2} T is perpendicular with the field will have an angular frequency of 6.5×10^{10} rad/s

The vector $d\vec{B}$ is perpendicular to $d\vec{l}$ (which points in the direction of the current) and to the unit vector \hat{r} directed from $d\vec{l}$ toward P.

The magnitude of $d\vec{B}$ is inversely proportional to r^2 , where r is the distance from $d\vec{l}$ to P.

The magnitude of $d\vec{B}$ is proportional to the current I and to the magnitude of the length element $d\vec{l}$.

The magnitude of $d\vec{B}$ is proportional to $\sin\theta$, where θ is the angle b/w \vec{r} and $d\vec{l}$.
