

**NAME: CHIOKE VICTOR  
U.P.**

**MATRIC NO:  
18/ENGO2/031**

**DEPARTMENT:  
COMPUTER  
ENGINEERING**

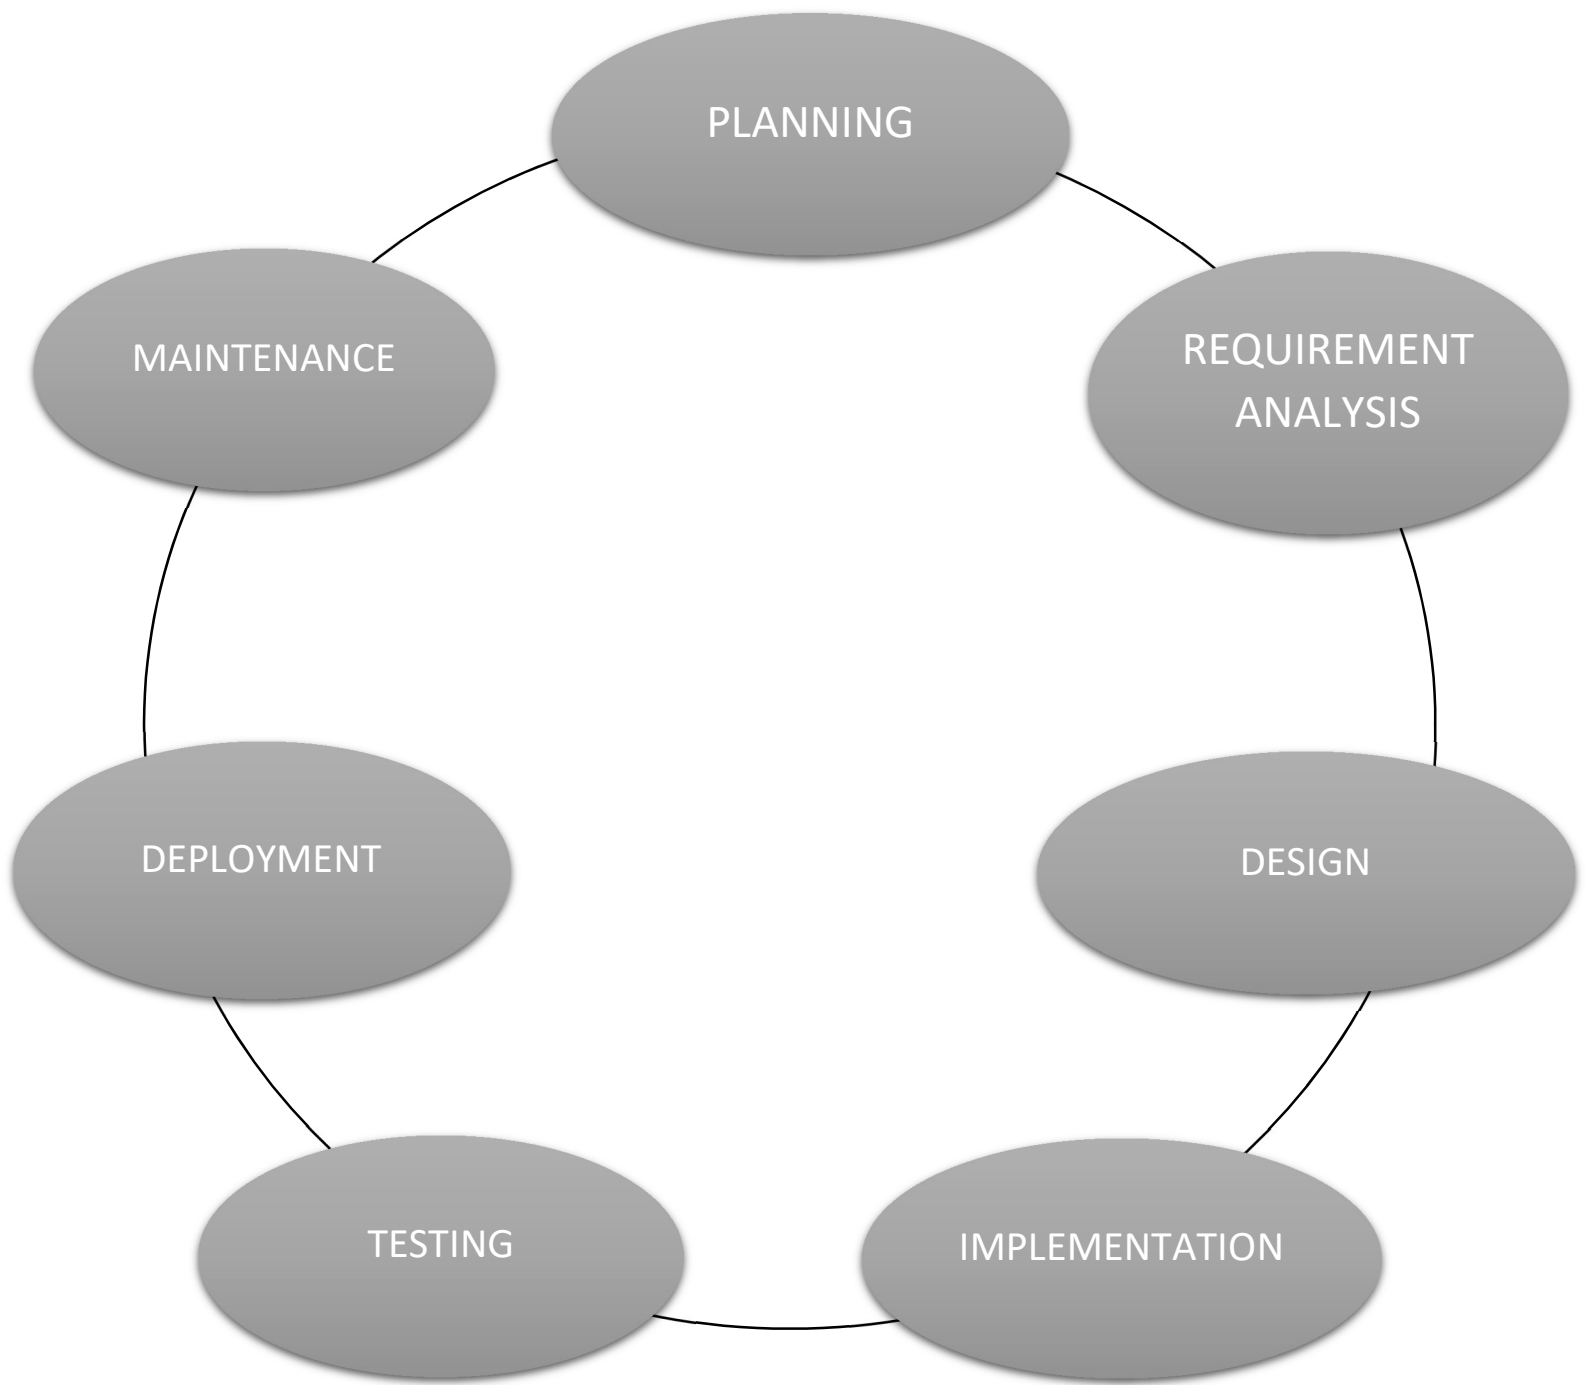

**TITLE: ENG 224  
ASSIGNMENT**

# **SOLUTION TO THE CLASSWORK GIVEN BELOW**

**A. The software development process is as follows**

- 1. Planning**
- 2. Requirement Analysis**
- 3. Design**
- 4. Implementation/coding**
- 5. Testing**
- 6. Deployment**
- 7. Maintenance**

**Following the cycle, we begin with the planning phase.**

## **PLANNING:-**

So, in this phase we identify the requirements of our employer.

They want the software to be able to:-

- i) Read the temperature of the soil
- ii) Determine its moisture content
- iii) Configure the time interval for the water system based on the above
- iv) Trigger alarms if water level is insufficient in the tank for irrigation
- v) Also to enable a password for the system

## **REQUIREMENT ANALYSIS:-**

We are to critically analyze the requirements and give more planning detail about each requirement of the software. Before we advance, the first and foremost is that we should put the code and make the software to integrate and initialize all parts of the machine in order for the whole system and its processes to be automated.

**a) Reading the temperature of the soil**

For this to be acquired, we are to initialize the machine to be able to use the soil thermometer and store the temperature as data

**b) Determine the moisture content of the soil**

The software will send signals to the moisture sensors which would calculate the exact amount of water that makes up the soil sample and show it on the screen.

**c) Configure the time interval for the water system based on the above**

The software would have another function to enable the water system and as well the irrigation sprinklers to water the soil at regular time intervals with the use of the day and night sensors placed around the farm.

**d) Trigger alarms if water level is insufficient in the tank for irrigation**

It would also be possible that before it starts the sprinklers, it would check the level of water in the tank with the use of the ultrasonic modules. These modules then measure the depth of the

tank and if it is below the water level indicator, it trigger an alarm and automatically pump water into the tank

e) Enable a password for the system

For security reasons, the admin would be made to log into the software with a password.

## **DESIGN:-**

In this phase, we take up the requirements of the users and begin to build up the interface of the software following our analysis. We would make use of special frameworks, libraries, Cascading Style Sheets (CSS), and also have the networking done between the software and the machine so as to achieve automation. The software would be designed in C and C++.

## **IMPLEMENTATION/CODING:-**

In this phase, the operations team would set up the hardware and be hosted as well. The developers would as well start to write the code needed for all exploits and the analyzers on the other hand, would also start making up test cases for test plans. Also the plumbers would be of importance here as to develop the water system for the farm

## **TESTING:-**

In the testing phase, we usually perform trial and error situations, perform debugging where ever there are flaws and rearrange the entire software to match the idea we setup if needed and to validate that all requirements have been met.

## **DEPLOYMENT:-**

In this phase, we see that we've made the ideal application with the requirements, we begin to set up the

hardware for the machine and henceforth it is ready to be launched.

## **MAINTENANCE:-**

Now that the software is being put to use and it is functioning properly, we need to ensure that the system is maintained recently. It involves the maintenance of the equipment, providing solutions to increase the speed and area of work if it is too slow or whether the sprinklers are not properly irrigating the soil. Plumbing maintenance and regular updates would be made to adjust to solve any issue the user has.

B.) The software and hardware features are below

- **Processor:**
  - 1.4 GHz
  - 32-bit (x86) processor
  
- **RAM:**
  - 2gb recommended
  
- **Operating System:**
  - Window XP or later
  
- **Disk Storage:** 4 GB of free disk space
  
- **Monitor Resolution:** Recommended: 320x260

## **C.) ALGORITHM**

**STEP 1: START**

**STEP 2: IS THE DAY/NIGHT SENSOR ON?**

**STEP 3: IF YES THEN CHECK THE WATER LEVEL OF THE TANK, IF NO START FROM BEGINNING**

**STEP 4: IS THE WATER LEVEL ABOVE THE INDICATOR?**

**STEP 5: IF YES, THEN TURN ON THE SPRINKLERS AND SEND A NOTIFICATION**

**STEP 6: IF NO, TRIGGER AN ALARM FOR 20 SECONDS AND START THE PUMP AND CHECK IF THE TANK IS FULL**

**STEP 7: IF TANK IS FULL, THEN STOP PUMP**

**STEP 8: IF NOT, THEN START THE PUMP AGAIN**

**STEP 9: MONITOR THE MOISTURE CONTENT OF THE SOIL**

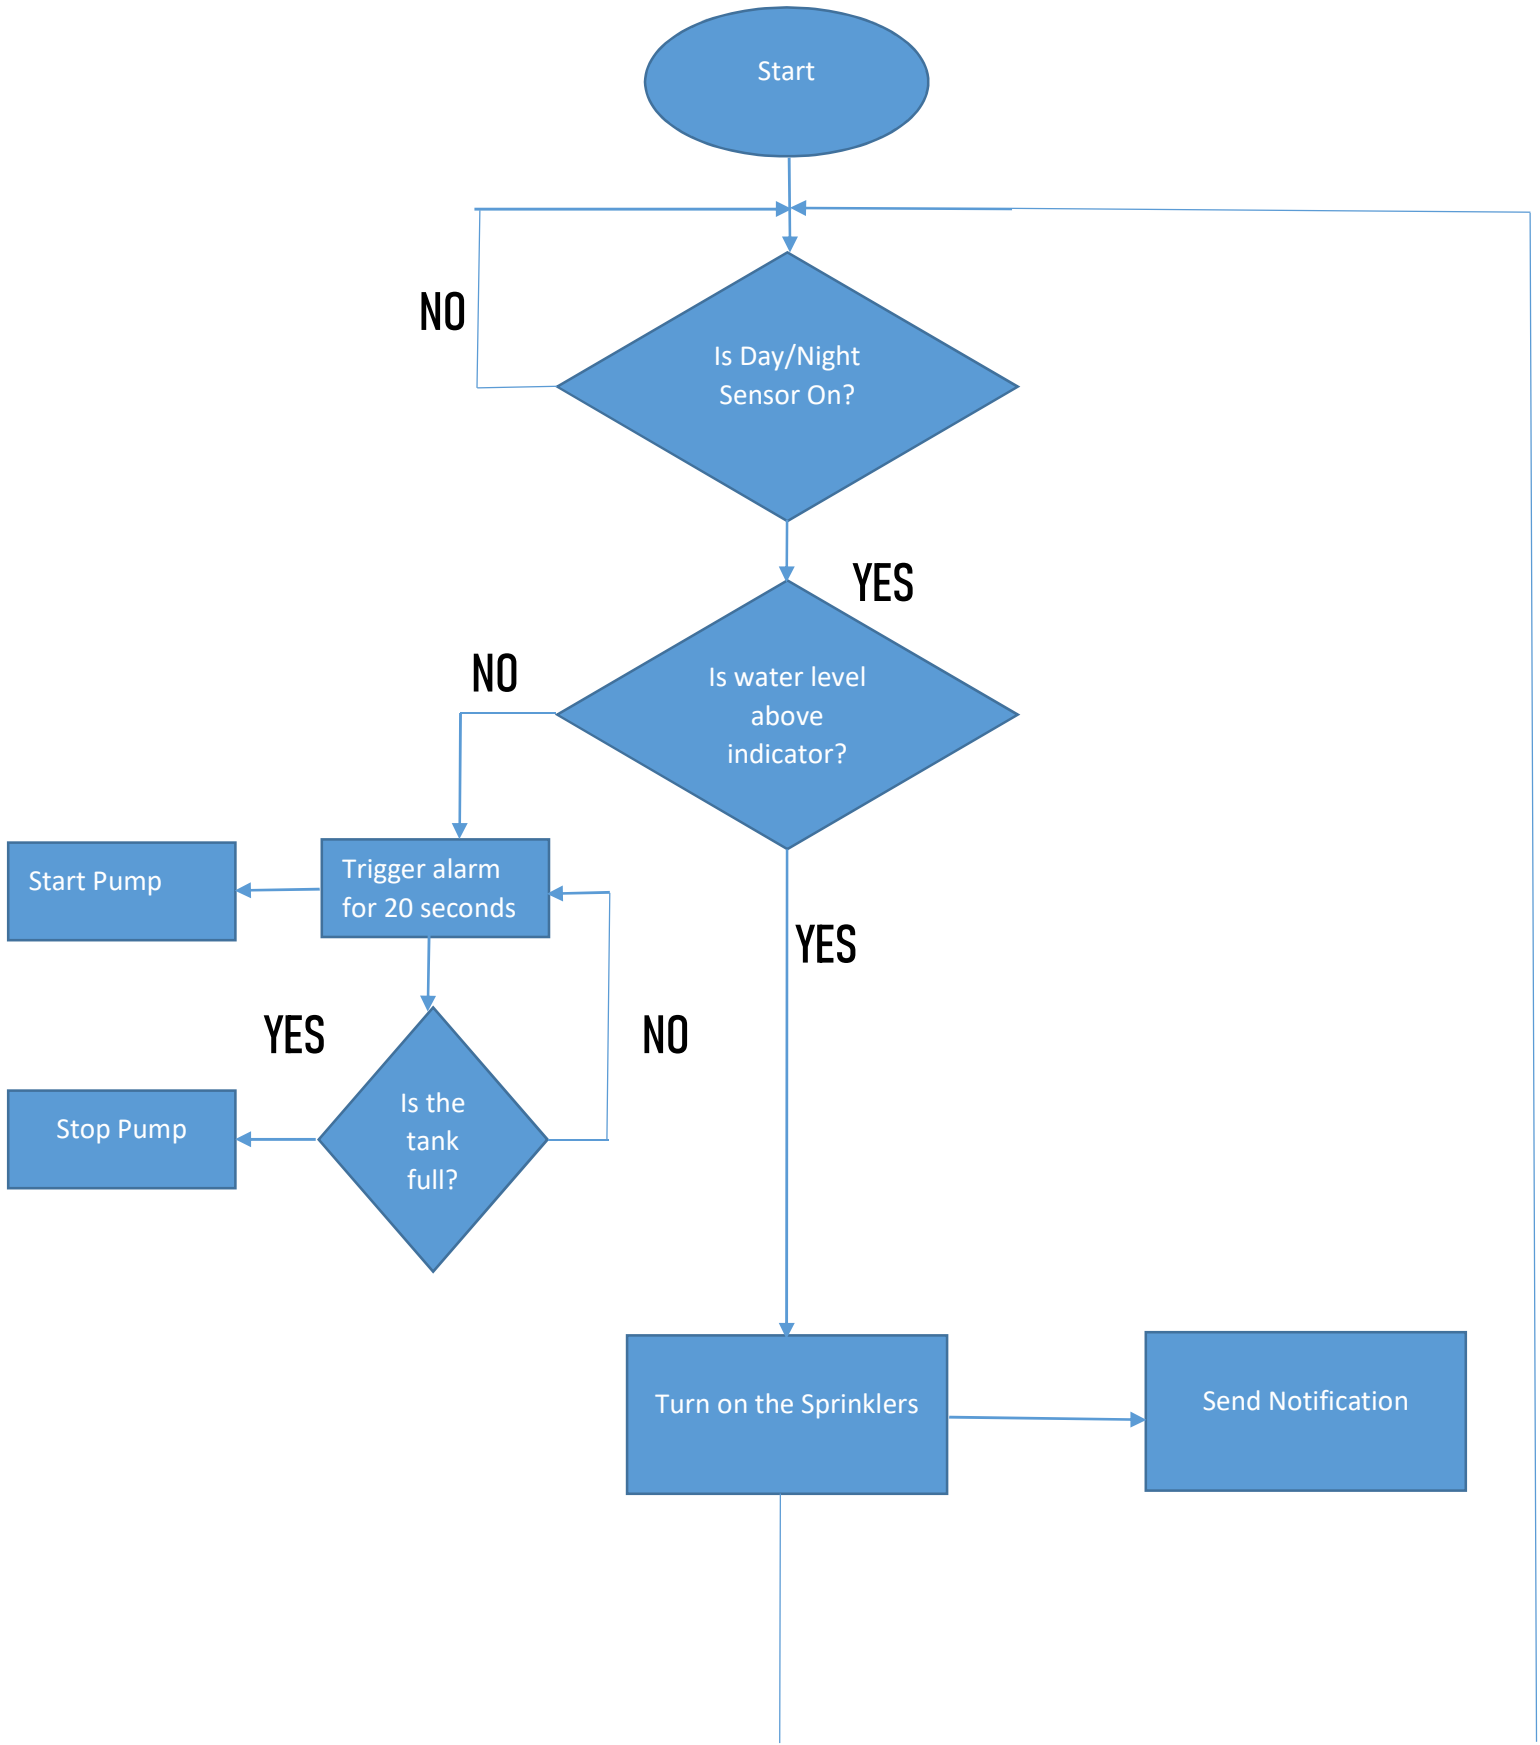

**STEP 10: IS THE MOISTURE LEVEL OKAY?**

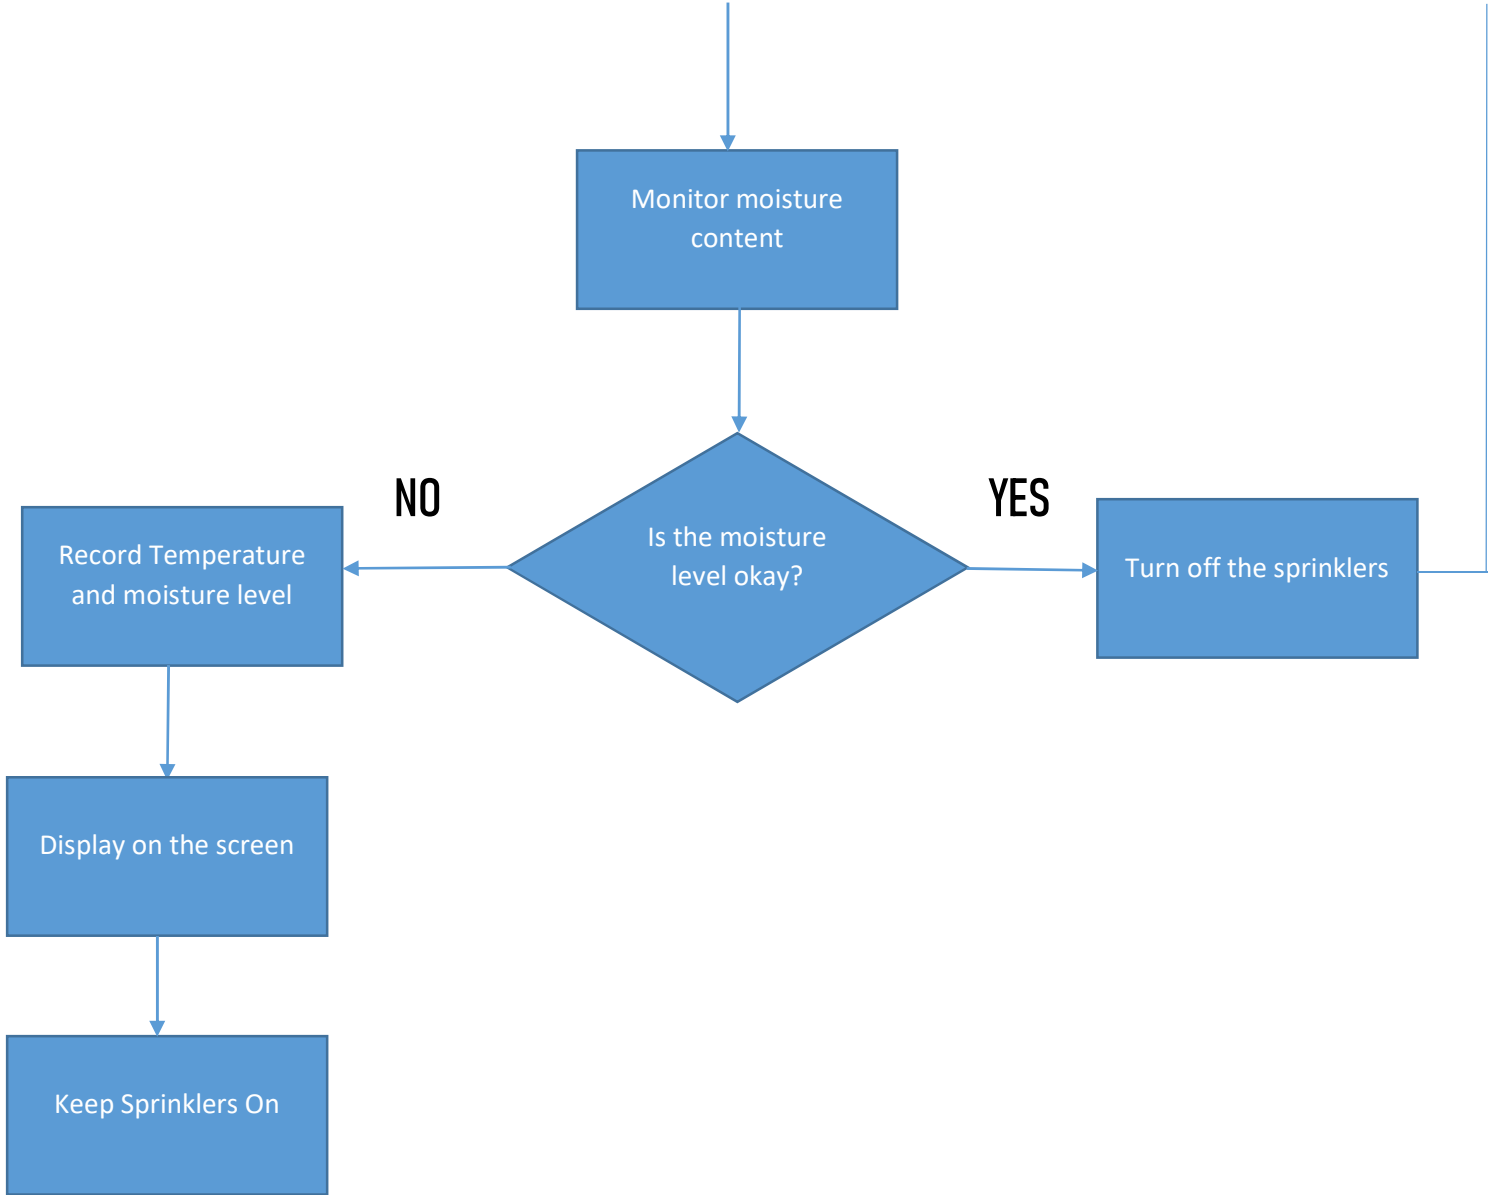

**STEP 11: IF YES THEN TURN OFF SPRINKLERS AND START FROM BEGINNING**

**STEP 12:** IF NO, THEN RECORD TEMPERATURE AND MOISTURE LEVEL AND  
DISPLAY ON THE SCREEN

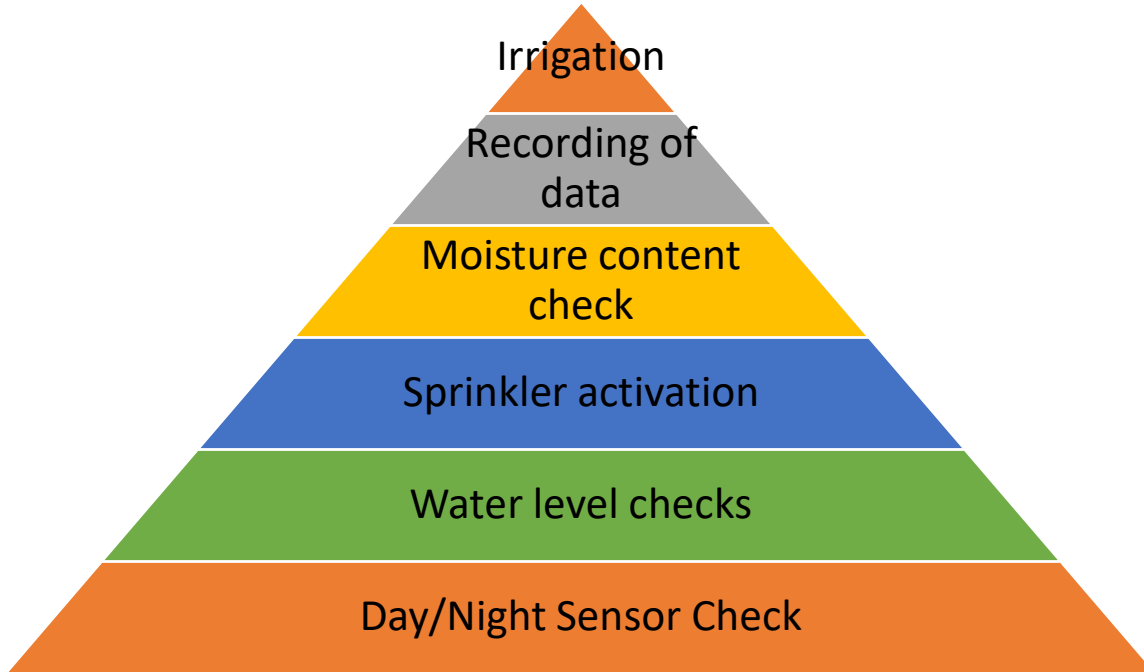

**STEP 13:** REPEAT

# FLOWCHART

## c.) BOTTOM-UP APPROACH

# TOP-DOWN APPROACH
